

# CMSC 132: Object-Oriented Programming II

---

## Design Patterns II

Department of Computer Science  
University of Maryland, College Park

# More Design Patterns

## ■ Marker interface

- Label semantic attributes of a class

## ■ Observer

- A way of notifying change to a number of classes

## ■ State

- Alter an object's behavior when its state changes

## ■ Visitor

- Defines a new operation to a class without changing class

# Marker Interface Pattern

## ■ Definition

- Label semantic attributes of a class

## ■ Where to use & benefits

- Need to indicate attribute(s) of a class
- Allows identification of attributes of objects without assuming they are instances of any particular class

# Marker Interface Pattern

## ■ Example

- Classes with desirable property GoodProperty
- Original
  - Store flag for GoodProperty in each class
- Using pattern
  - Label class using GoodProperty interface

## ■ Examples from Java

- Cloneable
- Serializable

# Marker Interface Example

```
public interface SafePet { } // no methods
```

```
class Dog implements SafePet { ... }
```

```
class Piranha { ... }
```

```
class d = new Dog();
```

```
class p = new Piranha();
```

```
if (d instanceof SafePet) ... // True
```

```
if (p instanceof SafePet) ... // False
```

# Observer Pattern

## ■ Definition

- Updates all dependents of object automatically once object changes state

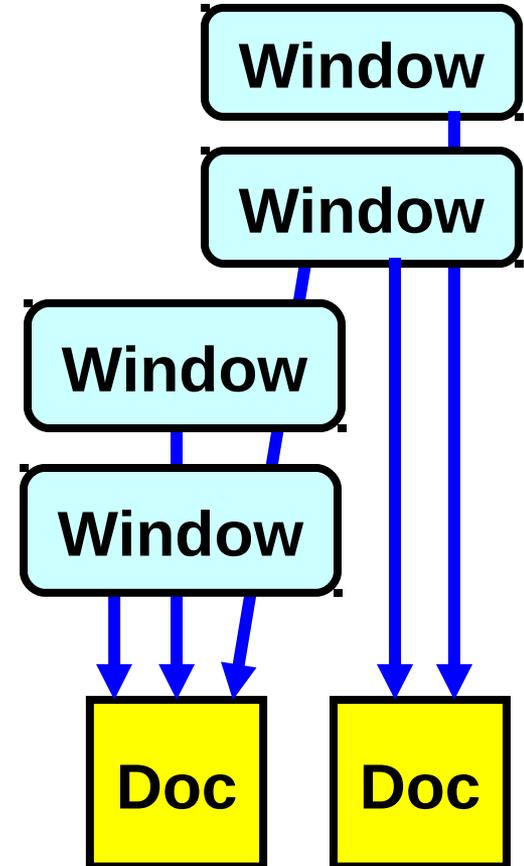

## ■ Where to use & benefits

- One change affects one or many objects
- Many object behavior depends on one object state
- Need broadcast communication
- Maintain consistency between objects
- Observers do not need to constantly check for changes

# Observer Pattern

## ■ Example

- Multiple windows (views) for single document
- Original
  - Each window checks document
  - Window updates image if document changes
  - Think of window as asking “Are we there yet?”
- Using pattern
  - Each window registers as observer for document
  - Document notifies all of its observers when it changes

# Observer Example

```
public interface Observer {  
    public void update(Observable o, Object a)  
        // called when observed object o changes  
}
```

```
public class Observable {  
    protected void setChanged()           // changed  
    protected void clearChanged()        // no change  
    boolean hasChanged()                 // return changed?  
  
    void addObserver(Observer o)         // track observers  
    void notifyObservers()               // notify if changed,  
    void notifyObservers(Object a)       // then clear change  
}
```

# Observer Example

```
public class MyWindow implements Observer {
    public openDoc(Observable doc) {
        doc.addObserver(this); // add window to list
    }
    public void update(Observable doc, Object arg) {
        redraw(doc); // display updated document
    }
}

public class MyDoc extends Observable {
    public void edit() {
        ... // edit document
        setChanged(); // mark change
        notifyObservers(arg); // invokes update()
    }
}
```

# State Pattern

## ■ Definition

- Represent change in an object's behavior using its member classes

## ■ Where to use & benefits

- Control states without many if-else statements
- Represent states using classes
- Every state has to act in a similar manner
- Simplify and clarify the program

# State Pattern

## ■ Example

- States representing finite state machine (FSM)

- Original

  - Each method chooses action depending on state

  - Behavior may be confusing, state is implicit

- Using pattern

  - State interface defines list of actions for state

  - Define inner classes implementing State interface

  - Finite state machine instantiates each state and tracks its current state

  - Current state used to choose action

# State Example – Original Code

```
public class FickleFruitVendor {  
    boolean wearingHat;  
    boolean isHatOn() { return wearingHat; }  
    String requestFruit() {  
        if (wearingHat) {  
            wearingHat = false;  
            return "Banana";  
        }  
        else {  
            wearingHat = true;  
            return "Apple";  
        }  
    }  
}
```

# State Example

```
public interface State {  
    boolean isHatOn();  
    String requestFruit();  
}
```

```
public class WearingHat implements State;  
public class NotWearingHat implements State;
```

# State Example

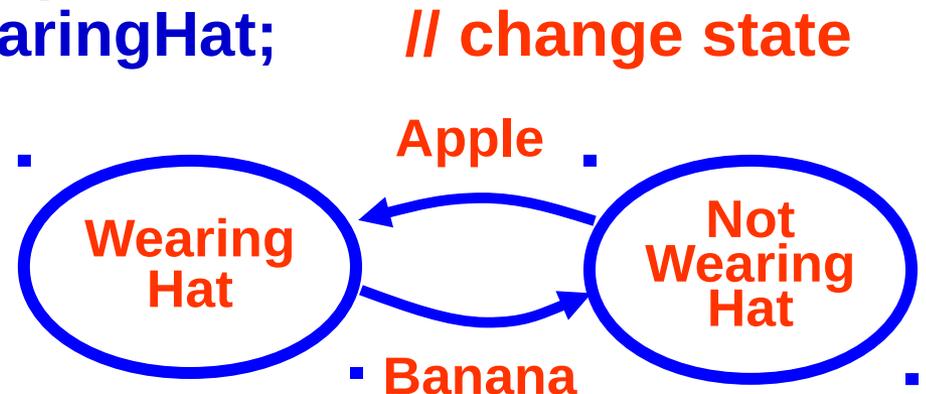

```
public class FickleFruitVendor {  
    State wearingHat = new WearingHat();  
    State notWearingHat = new NotWearingHat();  
  
    // explicitly track current state of Vendor  
    State currentState = wearingHat;  
  
    // behavior of Vendor depends on current state  
    public boolean isHatOn() {  
        return currentState.isHatOn();  
    }  
    public String requestFruit() {  
        return currentState.requestFruit();  
    }  
}
```

# State Example

```
class WearingHat implements State {  
    boolean isHatOn() { return true; }  
    String requestFruit() {  
        currentState = notWearingHat; // change state  
        return "Banana";  
    }  
}
```

```
class NotWearingHat implements State {  
    boolean isHatOn() { return false; }  
    String requestFruit() {  
        currentState = wearingHat; // change state  
        return "Apple";  
    }  
}
```

```
} // end class
```

# Visitor Pattern

## ■ Definition

- Define operations on elements of data structures without changing their classes

## ■ Where to use & benefits

- Add operations to classes with different interfaces
- Can modify operations on data structure easily
- Encapsulate operations on elements of data structure
- Decouples classes for data structure and algorithms
- Crossing class hierarchies may break encapsulation

# Visitor Pattern

## ■ Example

- Print elements in collection of objects

- Original

  - Iterator chooses action based on type of object

  - Many if-else statements

- Using pattern

  - Visitor interface defines actions during visit

  - Visitable interface allow objects to **accept** visit

  - Action automatically selected by polymorphic functions through **double dispatch**

# Visitor Example – Original Code

```
public void messyPrintCollection(Collection c) {  
    for (Object o : c) {  
        if (o instanceof String)  
            System.out.println("{"+o.toString()+"}"); // add { }  
        else if (o instanceof Float)  
            System.out.println(o.toString()+"f"); // add f  
        else  
            System.out.println(o.toString());  
    }  
}
```

# Visitor Example

```
public interface Visitor
{
    public void visit(VisitableString s);
    public void visit(VisitableFloat f);
}
```

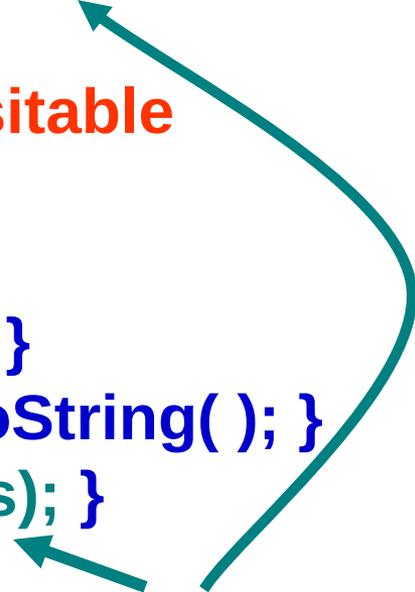

```
public interface Visitable
{
    public void accept(Visitor v);
}
```

# Visitor Example

```
public class VisitableString implements Visitable
{
    private String value;
    public VisitableString(String s) { value = s; }
    public String toString( ) { return value.toString( ); }
    public void accept(Visitor v) { v.visit(this); }
}
```

```
public class VisitableFloat implements Visitable
{
    private Float value;
    public VisitableFloat(Float f) { value = f; }
    public String toString( ) { return value.toString( ); }
    public void accept(Visitor v) { v.visit(this); }
}
```

**Double dispatch**

# Visitor Example

```
public class PrintVisitor implements Visitor
{
    public void visitCollection(Collection c) {
        for (Object o : c) {
            if (o instanceof Visitable)
                ((Visitable) o).accept(this);
            else
                System.out.println(o.toString());
        }
    }
    public void visit(VisitableString s) {
        System.out.println("{"+s.toString()+"}");
    }
    public void visit (VisitableFloat f) {
        System.out.println(f.toString()+"f");
    }
}
```

# UML Class Diagram of Abstract Visitor
